QUASIRECOGNITION BY THE PRIME GRAPH OF 
$L_3(q)$ WHERE $3 < q < 100$

Communicated by Ali Reza Ashrafi

Abstract. Let $G$ be a finite group. We construct the prime graph of $G$, which is denoted by $\Gamma(G)$ as follows: the vertex set of this graph is the prime divisors of $|G|$ and two distinct vertices $p$ and $q$ are joined by an edge if and only if $G$ contains an element of order $pq$. In this paper, we determine finite groups $G$ with $\Gamma(G) = \Gamma(L_3(q))$, $2 \leq q < 100$ and prove that if $q \neq 2, 3$, then $L_3(q)$ is quasirecognizable by the prime graph, i.e., if $G$ is a finite group with the same prime graph as the finite simple group $L_3(q)$, then $G$ has a unique non-Abelian composition factor isomorphic to $L_3(q)$. As a consequence of our results we prove that the simple group $L_3(4)$ is recognizable and the simple groups $L_3(7)$ and $L_3(9)$ are 2-recognizable by the prime graph.

1. Introduction

If $n$ is an integer, then we denote by $\pi(n)$ the set of all prime divisors of $n$. If $G$ is a finite group, then $\pi(|G|)$ is denoted by $\pi(G)$. We construct the prime graph of $G$, which is denoted by $\Gamma(G)$, as follows: the vertex set is $\pi(G)$ and two distinct vertices $p$ and $p'$ are joined by an edge if and only if $G$ has an element of order $pp'$ (we write $p \sim p'$).

Keywords: Prime graph, element order, simple group, linear group.

Let \( s(G) \) be the number of connected components of \( \Gamma(G) \) and let \( \pi_1, \pi_2, \ldots, \pi_{s(G)} \) be the connected components of \( \Gamma(G) \). If \( 2 \in \pi(G) \), then we always suppose \( 2 \in \pi_1 \).

The spectrum of a finite group \( G \), which is denoted by \( \pi_e(G) \) is the set of its element orders. It is clear that the set \( \pi_e(G) \) is closed and partially ordered by divisibility, and hence it is uniquely determined by \( \mu(G) \), the subset of its maximal elements.

A subset \( X \) of the vertices of a graph is called an independent set if the induced subgraph on \( X \) has no edge. Let \( G \) be a finite group and \( r \in \pi(G) \). We denote by \( \rho(G) \), some independent set of vertices in \( \Gamma(G) \) with the maximal number of elements. Also some independent set of vertices in \( \Gamma(G) \) containing \( r \) with the maximal number of elements is denoted by \( \rho(r, G) \). Also let \( t(G) = |\rho(G)| \) and \( t(r, G) = |\rho(r, G)| \).

Let \( G \) be a non-Abelian finite simple group. The numbers \( t(G) \) and \( t(r, G) \) have been determined in [34] and [36]. Also for every finite non-Abelian simple group, we use these references for adjacency of vertices in a prime graph of the group.

A finite group \( G \) is called recognizable by spectrum, if every finite group \( H \) with \( \pi_e(G) = \pi_e(H) \) is isomorphic to \( G \). A finite simple non-Abelian group \( P \) is called quasirecognizable by spectrum, if each finite group \( H \) with \( \pi_e(P) = \pi_e(H) \) has a unique non-Abelian composition factor isomorphic to \( P \) [2].

A finite group \( G \) is called recognizable by prime graph, if every finite group \( H \) with \( \Gamma(G) = \Gamma(H) \) is isomorphic to \( G \). A finite simple non-Abelian group \( P \) is called quasirecognizable by prime graph, if each finite group \( H \) with \( \Gamma(P) = \Gamma(H) \) has a unique nonabelian composition factor isomorphic to \( P \) [13].

We denote by \( k(\Gamma(G)) \) the number of isomorphism classes of the finite groups \( H \) satisfying \( \Gamma(G) = \Gamma(H) \). A finite group \( G \) is called \( n \)–recognizable by prime graph if \( k(\Gamma(G)) = n \) [16].

We note that quasirecognition by prime graph implies quasirecognition by spectrum, but the converse is not true in general. Also quasirecognition by prime graph is in general harder to establish than quasirecognition by spectrum, since some methods fail in the former case.

The structure of finite groups \( G \) such that \( \Gamma(G) \) is not connected has been determined by Gruenberg and Kegel (1975). Moreover it has been proved that \( s(G) \leq 6 \) and all the simple groups \( G \) such that \( \Gamma(G) \) is not connected have been described in [9, 24, 37].
We denote by \((a, b)\) the greatest common divisor of positive integers \(a\) and \(b\). If \(G\) is a finite group, then we denote by \(P_q\) a Sylow \(q\)–subgroup of \(G\).

Let \(\pi\) be a set of prime numbers and let \(G\) be a finite \(\pi\)–group. Then \(G\) has unique largest normal \(\pi\)–subgroup, which is denoted by \(O_{\pi}(G)\) and is called the \(\pi\)–radical of \(G\). In fact, \(O_{\pi}(G)\) contains every normal \(\pi\)–subgroup of \(G\). All further unexplained notations are standard and is referred to [4].

Finite groups \(G\) satisfying \(\Gamma(G) = \Gamma(H)\) have been determined, in cases where \(H\) is one of the following groups: a sporadic simple group [7]; a CIT simple group [12]; \(PSL(2, q)\), where \(q = p^{\alpha} < 100\) [11]; \(PSL(2, p)\), where \(p > 3\) is a prime [14]; \(G_2(7)\), \(2G_2(q)\), where \(q = 3^{2n+1} > 3\), \((n > 0)\) [13, 38]; \(PSL(2, q)\) [16, 17]; \(L_{16}(2)\) [18], \(B_p(3)\), where \(p\) is an odd prime [30].

Also, the quasirecognizability of the following simple non-Abelian groups by their prime graphs have been obtained: Alternating group \(A_p\) where \(p\) and \(p - 2\) are primes [15], \(L_9(2)\) [19], \(L_{10}(2)\) [20], \(2F_4(q)\) where \(q = 2^{2m+1}\) for some \(m \geq 1\), \(2D_p(3)\) where \(p = 2^n + 1 \geq 5\) is a prime [3], \(C_n(2)\), where \(n \neq 3\) is odd [5], \(L_n(2)\) and \(U_n(2)\), where \(n \geq 17\) [21].

In this paper we determine finite groups \(G\) such that \(\Gamma(G) = \Gamma(L_3(q))\), where \(q\) is a prime power and \(2 \leq q < 100\) and conclude that if \(3 < q < 100\), then \(L_3(q)\) is quasirecognizable by prime graph. As a consequence of our results we prove that the simple group \(L_3(4)\) is recognizable by prime graph and the simple groups \(L_3(7)\) and \(L_3(9)\) are 2–recognizable by prime graph. In fact the main theorem of our paper is as follow:

**Main Theorem.** Let \(q = p^{\alpha}\) be a prime power, \(L = L_3(q)\), where \(2 \leq q < 100\) and \(G\) be a finite group satisfying \(\Gamma(G) = \Gamma(L)\). Then \(G\) is one of the groups appeared in the second column of Table 1.
2. Preliminaries

We first quote some remarks and lemmas that are used in deducing the main theorem of this paper.

Remark 2.1. Let \( G \) be a finite group and \( K \) be a normal subgroup of \( G \). If \( p \sim q \) in \( \Gamma(G/K) \), then \( p \sim q \) in \( \Gamma(G) \). In fact if \( xK \in G/K \) has order \( pq \), then there is a power of \( x \) which has order \( pq \).

Remark 2.2. We know that \( \mu(L_2(q)) = \{p, (q-1)/d, (q+1)/d\} \), where \( q = p^a \) and \( d = (2, q-1) \), [8] (page. 213). By [28], \( \Gamma(L_3(q)) \) has two connected components: \( \pi_1(G) = \pi(p(q^2 - 1)) \) and \( \pi_2(G) = \pi((q^3 - 1)/(q - 1)(3, q - 1)) \). Also the set of element orders \( L_3(q) \), can be found in [26]; we have:

\[
\mu(L_3(q)) = \begin{cases} 
\{q - 1, \frac{1}{3}p(q - 1), \frac{1}{3}(q^2 - 1), \frac{1}{3}(q^2 + q + 1)\} & \text{if } d = 3, \\
\{p(q - 1), (q^2 - 1), (q^2 + q + 1)\} & \text{if } d = 1,
\end{cases}
\]

where \( q = p^a \) is odd number and \( d = (3, q - 1) \), and

\[
\mu(L_3(2^n)) = \begin{cases} 
\{4, 2^{n-1}, \frac{2}{3}(2^n - 1), \frac{1}{3}(2^{2n} - 1), \frac{1}{3}(2^{2n} + 2^n + 1)\} & \text{if } d = 3, \\
\{4, 2^{n-1}, 2^{2n} - 1, 2^{2n} - 1, 2^{2n} + 2^n + 1\} & \text{if } d = 1,
\end{cases}
\]

where \( d = (3, 2^n - 1) \).

Remark 2.3. Let \( p \) be a prime number and \( (a, p) = 1 \). Let \( k \geq 1 \) be the smallest positive integer such that \( a^k \equiv 1 \pmod{p} \). Then \( k \) is called the order of \( a \) with respect to \( p \) and we denote \( k \) by \( \text{ord}_p(a) \). Obviously by the Fermat little theorem \( \text{ord}_p(a) \mid (p - 1) \). Also, if \( a^n \equiv 1 \pmod{p} \), then \( \text{ord}_p(a) \mid n \).

Lemma 2.4. [31] Let \( G \) be a nonsolvable complement of a Frobenius group. Then \( G \) has a normal subgroup \( G_0 = SL(2, 5) \times Z \), such that \( |G : G_0| \leq 2 \), \( \pi(Z) \cap \{2, 3, 5\} = 1 \) and the Sylow subgroups of \( Z \) are cyclic.

Lemma 2.5. [33] Let \( G \) be a finite Frobenius group with kernel \( K \) and complement \( C \). Then

1. \( K \) is nilpotent,
2. The Sylow \( p \)-subgroups of \( C \) are cyclic if \( p > 2 \) and cyclic or generalized quaternion if \( p = 2 \).

Using [37, Theorem A], we can conclude the following lemma.

Lemma 2.6. A finite group \( G \) with disconnected prime graph \( \Gamma(G) \) satisfies one of the following conditions:

1. \( s(G) = 2 \), \( G = KC \) is a Frobenius group with kernel \( K \) and complement \( C \), and connected components of \( \Gamma(G) \) are \( \pi(K) \) and
Quasirecognition by the prime graph of $L_3(q)$ where $3 < q < 100$. Moreover, $K$ is nilpotent, hence $\pi(K)$ is a complete graph. If $C$ is solvable, then $\Gamma(C)$ is complete; otherwise, $2, 3, 5 \in \pi(G)$ and $\pi(C)$ can be obtained from the complete graph with vertex set $\pi(C)$ by removing the edge $3 \sim 5$.

(2) $s(G) = 2$ and $G$ is a 2-Frobenius group, i.e., $G = ABC$, where $A$ and $AB$ are normal subgroups of $G$, $B$ is a normal subgroup of $BC$, and $AB$ and $BC$ are Frobenius groups. The connected components of $\Gamma(G)$ are complete graphs $\Gamma(AC)$ and $\Gamma(B)$.

(3) There exists a finite non-Abelian simple group $S$ such that $G = G/K \leq \text{Aut}(S)$, where $K$ is a nilpotent normal subgroup of $G$; furthermore $K$ and $G/S$ are trivial or $\pi_1$-groups, $s(S) \geq s(G)$, and for every $2 \leq i \leq s(G)$, there exists $2 \leq j \leq s(S)$ such that $\pi_i(G) = \pi_j(S)$.

Remark 2.7. A 2-Frobenius group is solvable and the above lemma implies that $t(G) = 1$ or 2 for a solvable group.

Lemma 2.8. [35] Let $G$ be a finite group with $t(G) \geq 3$ and $t(2, G) \geq 2$. Then the followings hold:

1. There exists a finite non-Abelian simple group $S$ such that $G = G/K \leq \text{Aut}(S)$ for a maximal normal soluble subgroup $K$ of $G$.

2. For every independent subset $\rho$ of $\pi(G)$ with $|\rho| \geq 3$ at most one prime in $\rho$ divides the product $|K|, |G/S|$. In particular, $t(S) \geq t(G) - 1$.

3. One of the followings holds:
   a) every prime $r \in \pi(G)$ nonadjacent to 2 in $\Gamma(G)$ does not divide the product $|K|, |G/S|$; in particular, $t(2, S) \geq t(2, G)$;
   b) there exists a prime $r \in \pi(K)$ nonadjacent to 2 in $\Gamma(G)$; in which case $t(G) = 3$, $t(2, G) = 2$, and $S \cong A_7$ or $A_1(q)$ for some odd $q$.

Remark 2.9. Note that the condition of Lemma 2.8, implies an insolubility of $G$, and so by the Feit-Thompson Theorem, it is not necessary to assume in the main theorem, that $G$ is of even order.

Lemma 2.10. [30] Let $G$ be a finite group such that $s(G) \geq 2$ and $K$ a normal $\pi_1$-subgroup of $G$. Let $S$ be a finite simple group such that $S \leq G/K$ and $S$ is not a $\pi_1$-group. If $K \neq 1$, and $S$ contains a Frobenius subgroup with kernel $F$ and a cyclic complement $C$ such that $(|F|, |K|) = 1$, then $r|C| \in \pi_e(G)$, for every prime divisor $r$ of $|K|$.
Lemma 2.11. [22] Let $G$ be a group with disconnected prime graph, such that $t(G) \geq 3$. Also let $K$ be the maximal normal solvable subgroup of $G$. Then $K$ is a nilpotent $\pi_1$–group.

Lemma 2.12. [39] There are a total of 1972 isomorphism types of finite non-Abelian simple groups $G$ such that all prime divisors of $|G|$ do not exceed 1000.

The groups obtained by Lemma 2.12, are listed in Tables 1–4 of [39].

Let $t > 1$ and $n$ be natural numbers and let $\varepsilon \in \{+, -\}$. If there exists a prime that divides $t^n - (\varepsilon 1)^n$ and does not divide $t^i - (\varepsilon 1)^i$ for $1 \leq i < n$, then we denote this prime by $t_{[\varepsilon n]}$ and call it a primitive divisor of $t^n - (\varepsilon 1)^n$. A primitive divisor need not exist, nor be unique. The following lemma generalizes Zsigmondy's theorem:

Lemma 2.13. [29] Let $t, n > 1$ be natural numbers. Then, for all $\varepsilon \in \{+, -\}$, there exists a primitive divisor $t_{[\varepsilon n]}$ of $t^n - (\varepsilon 1)^n$ except in the following cases:

1. $\varepsilon = +$, $n = 6$, $t = 2$;
2. $\varepsilon = +$, $n = 2$ and $t = 2^l - 1$ for some $l \geq 2$;
3. $\varepsilon = -$, $n = 3$, $t = 2$;
4. $\varepsilon = -$, $n = 2$ and $t = 2^l + 1$ for some $l \geq 0$.

In the next lemma we write $L_{[\varepsilon n]}(q)$, where $\varepsilon \in \{+, -\}$, $L_{[\varepsilon n]}(q) = L_n(q)$ and $L_{[\varepsilon n]}(q) = U_n(q)$.

Lemma 2.14. [29] Suppose that $L_{[\varepsilon n]}(q)$ is a simple group for some natural numbers $n$ and $q$ and that the primitive prime divisor $r = q_{[\varepsilon n]}$ of $q^n - (\varepsilon 1)^n$ exists. Then $L_{[\varepsilon n]}(q)$ contains a Frobenius subgroup whose kernel is of order $r$ and cyclic complement is of order $n$. Moreover, if $n$ is odd or $q$ is even, then such a Frobenius subgroup exists in $SL_{[\varepsilon n]}(q)$.

Lemma 2.15. Let $q$ be a prime power and $L = L_3(q)$, where $2 < q < 100$. If $S$ is a non-Abelian simple group such that $\Gamma(S)$ is a subgraph of $\Gamma(L)$ and there exists $i \geq 2$ such that $\pi_2(L) = \pi_i(S)$, then $L \cong S$.

Proof. For every finite non-Abelian simple group, we use [34] and [36] for adjacency of vertices in a prime graph of the group. If $q \neq 41, 59, 71, 73, 89$ and 97, then $\pi(L_3(q)) \subseteq \{2, 3, ... , 997\}$. So the result follows from Lemma 2.12. Now suppose that $q = 89$ and $S$ is a non-Abelian simple group such that $\{2, 8011\} \subseteq \pi(S) \subseteq \{2, 3, 5, 11, 89, 8011\}$. According to the classification of finite simple groups we consider the following cases:
case 1. $S$ is isomorphic to an alternating group. Since $8011 \mid |S|$ and $7 \nmid |S|$, we get a contradiction.

case 2. $S$ is isomorphic to a sporadic simple group. Since $8011 \nmid |S|$, we get a contradiction.

case 3. $S$ is isomorphic to a simple group of Lie type. We use the list of orders of these groups given in [4]. If $S$ is defined over the field $F_q$, where $q = p^m$, then since $p \mid |S|$ we must have $p = 2, 3, 5, 11, 89$ or $8011$. We note that $\pi(S)$ contains all prime divisors of $q^2 - 1$, except $2B_2(q)$, where $q = 2^{2m+1}$.

If $p = 8011$, then $2003 \in \pi(8011^2 - 1) \subseteq \pi(q^2 - 1)$, which is a contradiction. So $p \neq 8011$.

If $p = 2$, then $ord_2(2) = 2, ord_5(2) = 4, ord_{11}(2) = 10, ord_{89}(2) = 11$ and $ord_{8011}(2) = 2670$. Thus $\max \{ord_r(2) \mid r \in \{3, 5, 11, 89, 8011\}\} = 2670$ and we have $2m \leq 2670$, for otherwise $2^{2m} - 1 = q^2 - 1$ would be divisible by a prime not in $\pi(S)$ by Lemma 2.13. Hence $m \leq 1335$. Since $2^3 - 1 = 7$, then $3 \nmid m$. The relations $2^4 + 1 = 17, 2^5 - 1 = 31, 2^7 - 1 = 127, 17 \mid 2^8 - 1, 73 \mid 2^9 - 1, 31 \mid 2^{10} - 1, 23 \mid 2^{11} - 1$ and Lemma 2.13 imply that $m \in \{1, 2, 1335\}$. By using the GAP-Program $2^{2670} - 1$ is not prime and there exists a prime $k \notin \{2, 3, 5, 11, 89, 8011\}$ such that $k \mid 2^{2670} - 1$. So $m = 1$ or 2. It is easy to check there is no possibility in this case.

If $p = 3$, then $ord_2(3) = 1, ord_5(3) = 4, ord_{11}(3) = 5, ord_{89}(3) = 88$ and $ord_{8011}(3) = 2670$. Thus $\max \{ord_r(3) \mid r \in \{2, 5, 11, 89, 8011\}\} = 2670$. As above, $m$ does not exceed 1335. Furthermore, $3 \nmid m$, since otherwise $13 \in \pi(3^3 - 1) \subseteq \pi(3^m - 1)$. The relations $3^4 + 1 = 2 \times 41, 61 \mid 3^5 + 1, 23 \mid 3^{88} - 1$ and Lemma 2.13 imply that $m \in \{1, 2, 1335\}$. By using the GAP-Program $3^{2670} - 1$ is not prime and there exists a prime $k \notin \{2, 3, 5, 11, 89, 8011\}$ such that $k \mid 3^{2670} - 1$. So $m = 1$ or 2. It is easy to check that there is no possibility in this case as well.

If $p = 5$, then $\max \{ord_r(5) \mid r \in \{2, 3, 11, 89, 8011\}\} = 445$. So similar to the previous case there is no possibility in this case as well.

If $p = 11$, then $\max \{ord_r(11) \mid r \in \{2, 3, 5, 89, 8011\}\} = 890$. So $m \leq 445$. It is easy to check that there is no possibility in this case, too.

If $p = 89$, then $\max \{ord_r(89) \mid r \in \{2, 3, 5, 11, 8011\}\} = 3$. So $m = 1$ and the only possibility is $S \cong L_3(89)$.

Similarly, we get our results for $q = 41, 59, 71, 73$ and 97. □

Corollary 2.16. Let $L = L_3(q)$, where $2 < q < 100$ and let $S$ be a finite simple group such that $\Gamma(S) = \Gamma(L)$. Then $S$ is isomorphic to $L$.

Proof. Straightforward from Lemma 2.15.
Remark 2.17. If $S$ is a finite simple group such that $\Gamma(S) = \Gamma(L_3(2))$, then $S$ isomorphic to $L_3(2)$ or $L_2(8)$, by Lemma 2.12.

In the following we give the structure of the group of outer automorphisms of the group $L_n(q)$.

Lemma 2.18. [23] Let $n \geq 3$, and $q = p^f$. Then $Out(L_n(q)) \cong \mathbb{Z}_{(n, q-1)} : \mathbb{Z}_f : \mathbb{Z}_2$.

By the above Lemma, we conclude that $Out(L_3(q)) \cong \mathbb{Z}_{(3, q-1)} : \mathbb{Z}_f : \mathbb{Z}_2$.

Lemma 2.19. [25] Let $L_3(q) < G \leq Aut(L_3(q))$, then $\Gamma(G)$ is not connected if and only if $G/L_3(q) \cong \langle \gamma \rangle \times \langle \beta \rangle$, where $\gamma$ and $\beta$ are field and graph automorphism, respectively.

By the above lemma, if $(3, q-1) = 3$, then $L_3(q)3$ has a connected prime graph. So $\Gamma(L_3(q)3)$ is not subgraph of $\Gamma(L_3(q))$.

Lemma 2.20. [32] Let $G$ be a finite group and let $K$ a nontrivial normal $p$-subgroup, for some prime $p$, and set $L = G/K$. Suppose that $L$ contains an element $x$ of order $m$ coprime to $p$ such that $\langle \varphi|_{\langle x \rangle} \cdot 1|_{\langle x \rangle} \rangle > 0$ for every Brauer character $\varphi$ of (an absolutely irreducible representation of) $L$ in characteristic $p$. Then $G$ contains elements of order $pm$.

3. Proof of the Main Theorem

Let $G$ be a finite group such that $\Gamma(G) = \Gamma(L_3(q))$, where $2 < q < 100$. By [34], we have $3 \leq t(G) \leq 4$ and $t(2, G) \geq 2$, except for $q = 3$. First, we consider this case separately.

The Case $L = L_3(3)$

By assumption $\Gamma(G) = \Gamma(L_3(3))$. So $s(G) = 2$ and we can apply Lemma 2.6. Suppose that $G$ is a Frobenius or 2-Frobenius group. If $G$ is nonsolvable, then $G$ is a Frobenius group by Remark 2.7. Hence the Frobenius complement of $G$ has a normal subgroup $SL_2(5) \times Z$ with index at most 2 by Lemma 2.4. Since $5 \notin \pi(G)$, we get a contradiction. Therefore $G$ is solvable Frobenius or 2-Frobenius group. We note that there exists a finite Frobenius group $G$ with $\Gamma(G) = \Gamma(L_3(3))$. Indeed, let $H$ be an extension of the group of order 2 by $S_4$ such that the Sylow 2-subgroup in $H$ is a generalized quaternion group. Then $\mu(H) = \{6, 8\}$. By Lemma 8 in [27], there is a Frobenius group $G$ which is an extension of an elementary Abelian 13-group by $H$. Then $\mu(G) = \{6, 8, 13\} = \mu(L_3(3))$. 

Therefore we conclude that $\Gamma(G) = \Gamma(L_3(3))$. Also, we note that there exists a finite 2-Frobenius group $G$ of order $3^6.13.2$ such that $\Gamma(G) = \Gamma(L_3(3))$. Now suppose that there exists a finite non-Abelian simple group $S$ such that $S \leq G/K \leq Aut(S)$, where $K$ is a $\pi_1$-group and nilpotent normal subgroup of $G$. It follows from Lemma 2.15, that $S \cong L_3(3)$. Since $Out(L_3(3)) \cong \mathbb{Z}_2$ by Lemma 2.18, then $G/L_3(3) \leq \mathbb{Z}_2$. Therefore $G/O_\pi(G) \cong L_3(3)$ or $L_3(3).2$, where $\pi \subseteq \{2, 3\}$.

If $q \neq 3$, then $t(G) \geq 3$ and $t(2, G) \geq 2$. By Lemmas 2.8 and 2.11, there exists a finite non-Abelian simple group $S$ such that $S \leq G/K \leq Aut(S)$ for the maximal normal solvable subgroup $K$ of $G$, and $K$ is nilpotent $\pi_1$-group.

**Case L = L_3(2)**

It follows from Remark 2.17, that $S \cong L_3(2)$ or $L_2(8)$. At first, suppose that $S \cong L_3(2)$. We know that $Out(L_3(2)) \cong \mathbb{Z}_2$, by Lemma 2.18. Then $G/L_3(2) \leq \mathbb{Z}_2$. By [4], $L_3(2)2$ has an element of order 6, so $\Gamma(L_3(2))$ is not subgraph of $\Gamma(G)$. So we have $G = G/K \cong L_3(2)$, where $K$ is a nilpotent 2-group. By [4], we know that $L_3(2)$ contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3. If $2 \in \pi(K)$, then by Lemma 2.10, $2 \sim 3$ in $\Gamma(G)$, which is a contradiction. Therefore $K = 1$ and in this case we have $G \cong L_3(2)$. Now suppose that $S \cong L_2(8)$. We note that $Out(L_2(8)) \cong \mathbb{Z}_3$. Then $G/L_2(8) \leq \mathbb{Z}_3$. Since $L_2(8).3$ has an element of order 6, then $\Gamma(L_2(8))3$ is not subgraph of $\Gamma(G)$. So we have $G/K \cong L_2(8)$. Therefore, $G/O_2(G) \cong L_2(8)$.

**Case L = L_3(4)**

It follows from Lemma 2.15, that $S \cong L_3(4)$. We know that $Out(L_3(4)) \cong \mathbb{Z}_3 : \mathbb{Z}_2 : \mathbb{Z}_2 \cong \mathbb{Z}_2 \times S_3$, and so $G/L_3(4) \leq Out(L_3(4)) \cong \mathbb{Z}_2 \times S_3$. By the notations of [4], the finite groups $L_3(4).2_1$, $L_3(4).3$, $L_3(4).6$ $L_3(4).2_2 \cong L_3(4).2_3^a \cong L_3(4).2_3^b$ and $L_3(4).2_3 \cong L_3(4).2_3^a \cong L_3(4).2_3^b$ have elements of order 6. Then the prime graphs of these groups are not subgraphs of $\Gamma(G)$. So $G/K \cong L_3(4)$, where $K$ is a nilpotent 2-group. We note that $L_3(2)$ is a maximal subgroup of $L_3(4)$ and contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3, by [4]. If $2 \in \pi(K)$, then by Lemma 2.10, $2 \sim 3$ in $\Gamma(G)$, which is a contradiction. Hence $K = 1$ and $G \cong L_3(4)$. Therefore $L_3(4)$ is recognizable by its prime graph.

</table>
Case $L = L_3(5)$

It follows from Lemma 2.15, that $S \cong L_3(5)$. Then $G/L_3(5) \leq Out(L_3(5)) \cong \mathbb{Z}_2$. So we have $G/K \cong L_3(7)$ or $L_3(7).2$, where $K$ is a nilpotent $\{2,3,5\}$-group. We note that $L_3(5)$ contains a Frobenius subgroup with Frobenius kernel of order 31 and Frobenius complement of order 3 by Lemma 2.14. If $5 \in \pi(K)$, then by Lemma 2.10, $3 \sim 5$ in $\Gamma(G)$, which is a contradiction. If $3 \in \pi(K)$, then let $P \in Syl_3(K)$ and $Q \in Syl_3(G)$. Since $K$ is a nilpotent group, then $P$ char $K$. On the other hand, Since $K \leq G$ we can conclude that $P \leq G$. Since $3 \not\sim 5$ in $\Gamma(G)$, then $Q$ acts fixed point free on $P$. Thus $PQ$ is a Frobenius group, with Frobenius kernel $P$ and Frobenius complement $Q$. Therefore $Q$ is cyclic by Lemma 2.5. This is a contradiction, since $L_3(5)$ has no element of order $5^3$, by Remark 2.2. Therefore we have $G/O_2(G) \cong L_3(5)$ or $L_3(5).2$.

Case $L = L_3(7)$

It follows from Lemma 2.15, that $S \cong L_3(7)$. We know that $Out(L_3(7)) \cong \mathbb{Z}_3 : \mathbb{Z}_2 \cong S_3$. Then $G/L_3(7) \leq S_3$. By Lemma 2.19, $L_3(7).3$ has a connected prime graph, and so $\Gamma(L_3(7).3)$ is not a subgraph of $\Gamma(G)$. Hence we have $G/K \cong L_3(7)$ or $L_3(7).2$, where $K$ is a nilpotent $\{2,3,7\}$-group. We know that $L_3(7)$ contains a Frobenius subgroup with Frobenius kernel of order 19 and Frobenius complement of order 3, by Lemma 2.14. If $7 \in \pi(K)$, then by Lemma 2.10, $3 \sim 7$ in $\Gamma(G)$, which is a contradiction. If $3 \in \pi(K)$, then let $P \in Syl_3(K)$ and $Q \in Syl_7(G)$. Since $3 \not\sim 7$ in $\Gamma(G)$, then $Q$ acts fixed point free on $P$. Thus $PQ$ is a Frobenius group, with Frobenius kernel $P$ and Frobenius complement $Q$. Therefore $Q$ is cyclic by Lemma 2.5. This is a contradiction, since $L_3(7)$ has no element of order $7^3$, by Remark 2.2. If 2 $\in \pi(K)$, then let $x \in G/K$, $X = \langle x \rangle$ and $o(x) = 19$ and $z = exp(2\pi i/19)$. Now by using [10] about the irreducible characters of $L_3(7)$ (mod 2), we can see that $\langle \varphi_i \mid X, 1 \mid x \rangle = (1 + 1 \times 18)/19 = 1 > 0, \langle \varphi_2 \mid X, 1 \mid x \rangle = (56 + (-1) \times 18)/19 = 2 > 0, \langle \varphi_3 \mid X, 1 \mid x \rangle = (152 + 0 \times 18)/19 = 8 > 0$.

for $i = 3,4,5, \langle \varphi_j \mid X, 1 \mid x \rangle = (288 + (z + z^7 + z^{11}) + (z^{-1} + z^-7 + z^{-11}) + (z^2 + z^{14} + z^{22}) + (z^{-2} + z^{-14} + z^{-22}) + (z^4 + z^{28} + z^{44}) + (z^{-4} + z^{-28} + z^{-44}) \times 3)/19 = (288 + (\sum_{i=1}^{18} z^i) \times 3)/19 = (288 + (-1) \times 3)/19 = 15 > 0$ for $j = 6,7,\ldots,11$ and $\langle \varphi_{12} \mid X, 1 \mid x \rangle = (342 \times 0 \times 18)/19 = 18 > 0$. Therefore for every irreducible character $\varphi$ of $L_3(7)$ (mod 2) we show that $\langle \varphi \mid X, 1 \mid x \rangle = \sum_{x \in X} \varphi(x)/|X| > 0$. Now by using Lemma 2.20, it follows that $38 \in \pi_3(G)$. Then $2 \sim 19$ in $\Gamma(G)$, which is a contradiction. Therefore $G \cong L_3(7)$ or $L_3(7).2$ and $k(\Gamma(L_3(7))) = 2$. 

Case $L = L_3(8)$

It follows from Lemma 2.15, that $S \cong L_3(8)$. We note that $\text{Out}(L_3(8)) \cong \mathbb{Z}_3 \times \mathbb{Z}_2 \cong \mathbb{Z}_6$. Since $L_3(8).2$, $L_3(8).3$ and $L_3(8).6$ have elements of order 6, then $\Gamma(L_3(8).2)$, $\Gamma(L_3(8).3)$ and $\Gamma(L_3(8).6)$ are not subgraphs of $\Gamma(G)$. So we have $G/K \cong L_3(8)$, where $K$ is a nilpotent $\{2,3,7\}$-group. We know that $L_3(8)$ contains a Frobenius subgroup with Frobenius kernel of order 73 and Frobenius complement of order 3, by Lemma 2.14. If $2 \in \pi(K)$, then by Lemma 2.10, $2 \sim 3$ in $\Gamma(G)$, which is a contradiction. If $3 \in \pi(K)$, then let $P \in Syl_3(K)$ and $Q \in Syl_7(G)$. Since $3 \not\sim 7$ in $\Gamma(G)$, then $Q$ acts fixed point free on $P$. Thus $PQ$ is a Frobenius group, with Frobenius kernel $P$ and Frobenius complement $Q$. Therefore $Q$ is cyclic by Lemma 2.5. This is a contradiction, since $L_3(8)$ has no element of order $7^3$, by Remark 2.2. Therefore $G/O_7(G) \cong L_3(8)$.

Case $L = L_3(9)$

It follows from Lemma 2.15, that $S \cong L_3(9)$. We note that $\text{Out}(L_3(9)) \cong \mathbb{Z}_2 \times \mathbb{Z}_2$. Since $L_3(9).2$ and $L_3(9).3$, have elements of order 26 and 14 respectively, then $\Gamma(L_3(9).2)$ and $\Gamma(L_3(9).3)$ are not subgraphs of $\Gamma(G)$. So we have $G/K \cong L_3(9)$ or $L_3(9).21$, where $K$ is a nilpotent $\{2,3,5\}$-group. We know that $L_3(9)$ contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3, by Lemma 2.14. If $5 \in \pi(K)$, then by Lemma 2.10, $3 \sim 5$ in $\Gamma(G)$, which is a contradiction. We may assume that $K$ is an elementary Abelian $p$-group for $p \in \{2,3\}$. If $2 \in \pi(K)$, then let $x \in G/K$, $X = \langle x \rangle$, $o(x) = 7$. Now by using [10] about the irreducible characters of $L_3(9)$ (mod 2), we can see that $\langle \varphi_1 |_X, 1 |_X \rangle = (1 + 1 \times 6)/7 = 1 > 0$, $\langle \varphi_2 |_X, 1 |_X \rangle = (90 + (1) \times 6)/7 = 12 > 0$, $\langle \varphi_3 |_X, 1 |_X \rangle = \langle \varphi_4 |_X, 1 |_X \rangle = (640 + 3\times 1(-1 + i\sqrt{7}))/7 = 640/7 = 91 > 0$, $\langle \varphi_i |_X, 1 |_X \rangle = (640 + 3 \times 6)/7 = 94 > 0$ for $i = 5, 6, 7, 8$, similarly $\langle \varphi_j |_X, 1 |_X \rangle = (640 + 3\times 1(-1 + i\sqrt{7}))/7 = 640/7 = 91 > 0$ for $j = 9, \ldots, 32$, $\langle \varphi_33 |_X, 1 |_X \rangle = \langle \varphi_34 |_X, 1 |_X \rangle = \langle \varphi_35 |_X, 1 |_X \rangle = (728 + 0 \times 6)/7 = 104 > 0$. Therefore for every irreducible character $\varphi$ of $L_3(9)$ (mod 2) we show that $\langle \varphi |_X, 1 |_X \rangle = \sum_{x \in X} \varphi(x)/|X| > 0$. Now by using Lemma 2.20, it follows that $14 \in \pi_e(G)$. Then $2 \sim 7$ in $\Gamma(G)$, which is a contradiction. If $3 \in \pi(K)$, then let $x \in G/K$, $X = \langle x \rangle$, $o(x) = 5$. Now by [10], we can check easily $\langle \varphi |_X, 1 |_X \rangle = \sum_{x \in X} \varphi(x)/|X| > 0$ for every irreducible character $\varphi$ of $L_3(9)$ (mod 3). By Lemma 2.20, it follows that $15 \in \pi_e(G)$. Then
3 \sim 5 \in \Gamma(G), which is a contradiction. Hence \( K = 1 \) and \( G \cong L_3(9) \) or \( L_3(9).2_1 \). Therefore \( k(\Gamma(L_3(9))) = 2 \).

The proof of the other cases are similar and for convenience, we give some of them, namely \( L_3(11), L_3(13), L_3(16), L_3(25) \) and \( L_3(32) \).

**Case \( L = L_3(11) \)**

It follows from Lemma 2.15, that \( S \cong L_3(11) \). We know that \( \text{Out}(L_3(11)) \cong \mathbb{Z}_2 \). Then \( G/L_3(11) \leq \mathbb{Z}_2 \). So we have \( G/K \cong L_3(11) \) or \( L_3(11).2 \), where \( K \) is a nilpotent \( \{2, 3, 5, 11\} \)-group. We know that \( L_3(11) \) contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3 by Lemma 2.14. If \( 11 \in \pi(K) \), then by Lemma 2.10, \( 3 \sim 11 \) in \( \Gamma(G) \), which is a contradiction. If \( 3 \in \pi(K) \), then let \( P \in \text{Syl}_3(K) \) and \( Q \in \text{Syl}_{11}(G) \). We know that \( 3 \not\sim 11 \) in \( \Gamma(G) \). So \( Q \) acts fixed point free on \( P \). Thus \( PQ \) is a Frobenius group, with Frobenius kernel \( P \) and Frobenius complement \( Q \). Therefore \( Q \) is cyclic by Lemma 2.5. This is a contradiction, since \( L_3(11) \) has no element of order \( 11^3 \). Therefore \( G/O_2(G) \cong L_3(11) \) or \( L_3(11).2 \), where \( \pi \subseteq \{2, 5\} \).

**Case \( L = L_3(13) \)**

It follows from Lemma 2.15, that \( S \cong L_3(13) \). We know that \( \text{Out}(L_3(13)) \cong \mathbb{Z}_3 : \mathbb{Z}_2 \), by Lemma 2.18. By Lemma 2.19, \( L_3(13).3 \) has a connected prime graph, and so \( \Gamma(L_3(13).3) \) is not subgraph of \( \Gamma(G) \). Hence \( G/L_3(13) \leq \mathbb{Z}_2 \), and so \( G/K \leq L_3(13).2_2 \), where \( K \) is a nilpotent \( \{2, 3, 7, 13\} \)-group. We know that \( L_3(13) \) contains a Frobenius subgroup with Frobenius kernel of order 61 and Frobenius complement of order 3 by Lemma 2.14. If \( 13 \in \pi(K) \), then by Lemma 2.5, \( 3 \not\sim 13 \) in \( \Gamma(G) \). Similarly \( 7 \notin \pi(K) \). If \( 3 \in \pi(K) \), then let \( P \in \text{Syl}_3(K) \) and \( Q \in \text{Syl}_{13}(G) \). We know that \( 3 \not\sim 13 \) in \( \Gamma(G) \). So \( Q \) acts fixed point free on \( P \). Thus \( PQ \) is a Frobenius group, with Frobenius kernel \( P \) and Frobenius complement \( Q \). Therefore \( Q \) is cyclic by Lemma 2.5. This is a contradiction, since \( L_3(13) \) has no element of order \( 13^3 \). Therefore \( G/O_2(G) \leq L_3(13).2_2 \).

**Case \( L = L_3(16) \)**

It follows from Lemma 2.15, that \( S \cong L_3(16) \). We know that \( \text{Out}(L_3(16)) \cong \mathbb{Z}_3 : \mathbb{Z}_4 : \mathbb{Z}_2 \), by Lemma 2.18. By Lemma 2.19, \( L_3(16).3 \) has a connected prime graph, and so \( \Gamma(L_3(16).3) \) is not a subgraph of \( \Gamma(G) \). Hence
\[ \mathcal{G}/L_3(16) \leq (\mathbb{Z}_4 \times \mathbb{Z}_2), \text{ and so } G/K \leq L_3(16).(\mathbb{Z}_4 \times \mathbb{Z}_2), \text{ where } K \text{ is a nilpotent } \{2, 3, 5, 17\}-\text{group.} \]

We know that \( L_3(16) \) contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3 by Lemma 2.14. If \( 2 \in \pi(K) \), then by Lemma 2.10, \( 2 \sim 3 \) in \( \Gamma(G) \), which is a contradiction. Since \( S \ncong A_7, A_1(q) \) and \( 2 \not\sim 3 \) in \( \Gamma(G) \), then by Lemma 2.8, we have \( 3 \nmid |K||\mathcal{G}/L_3(16)| \). So \( 3 \notin \pi(K) \). Similarly, \( 17 \notin \pi(K) \). Therefore \( G/O_5(G) \leq L_3(16).(\mathbb{Z}_4 \times \mathbb{Z}_2) \).

**Case** \( L = L_3(25) \)

It follows from Lemma 2.15, that \( S \cong L_3(25) \). We know that \( Out(L_3(25)) \cong \mathbb{Z}_3 : \mathbb{Z}_2 : \mathbb{Z}_2 \), by Lemma 2.18. By Lemma 2.19, \( L_3(25).3 \) has a connected prime graph, and so \( \Gamma(L_3(25).3) \) is not a subgraph of \( \Gamma(G) \). Hence \( \mathcal{G}/L_3(25) \leq (\mathbb{Z}_2 \times \mathbb{Z}_2), \text{ where } K \text{ is a nilpotent } \{2, 3, 5, 13\}-\text{group.} \)

We know that \( L_3(25) \) contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3 by Lemma 2.14. If \( 5 \in \pi(K) \), then by Lemma 2.10, \( 3 \sim 5 \) in \( \Gamma(G) \), which is a contradiction. Similarly, \( 13 \in \pi(K) \). If \( 3 \in \pi(K) \), then let \( P \in Syl_3(K) \) and \( Q \in Syl_5(G) \). We know that \( 3 \not\sim 5 \) in \( \Gamma(G) \). So \( Q \) acts fixed point free on \( P \). Thus \( PQ \) is a Frobenius group, with Frobenius kernel \( P \) and Frobenius complement \( Q \). Therefore \( Q \) is cyclic by Lemma 2.5. This is a contradiction, since \( L_3(25) \) has no element of order 5^4. Therefore, \( G/O_2(G) \leq L_3(25).(\mathbb{Z}_2 \times \mathbb{Z}_2) \).

**Case** \( L = L_3(32) \)

It follows from Lemma 2.15, that \( S \cong L_3(32) \). We know that \( Out(L_3(32)) \cong \mathbb{Z}_5 \times \mathbb{Z}_2 \cong \mathbb{Z}_{10} \). Hence \( \mathcal{G}/L_3(32) \leq \mathbb{Z}_{10} \) and so \( G/K \leq L_3(32).\mathbb{Z}_{10} \).

We know that \( L_3(32) \) contains a Frobenius subgroup with Frobenius kernel of order 7 and Frobenius complement of order 3 by Lemma 2.14. If \( 2 \in \pi(K) \), then by Lemma 2.10, \( 2 \sim 3 \) in \( \Gamma(G) \), which is a contradiction. Since \( S \ncong A_7, A_1(q) \) and \( 2 \not\sim 3 \) in \( \Gamma(G) \), then by Lemma 2.8, we have \( 3 \nmid |K||\mathcal{G}/L_3(32)| \). So \( 3 \notin \pi(K) \). Similarly, \( 11 \notin \pi(K) \). Therefore \( G/O_{31}(G) \leq L_3(32).\mathbb{Z}_{10} \).

By the main theorem and definitions of recognizability, quasirecognizability and \( n \)-recognizability of prime graph, we can conclude the following corollaries.

**Corollary 3.1.** The finite simple group \( L_3(q) \) for \( 3 < q < 100 \) is quasirecognizable by its prime graph.
Corollary 3.2. The finite simple group $L_3(4)$ is recognizable by its prime graph and the finite simple groups $L_3(7)$ and $L_3(9)$ are $2-$recognizable by its prime graph.

By [27], we know that the simple groups $L_3(3)$ is not recognizable by spectrum, and so it is not recognizable by its prime graph. It seems that if $p \geq 7$ is a prime number, then the simple group $L_3(p)$ is $2-$recognizable by its prime graph. Finally, we pose the following problem:

**Problem:** Is the simple group $L_3(p)$, $2-$recognizable by its prime graph, where $p \geq 7$ is a prime number?
