Title:

Continuous dependence on coefficients for stochastic evolution equations with multiplicative Lévy Noise and monotone nonlinearity

(Communicated by Hamid Pezeshk)

ABSTRACT. Semilinear stochastic evolution equations with multiplicative
Lévy noise are considered. The drift term is assumed to be monotone
nonlinear and with linear growth. Unlike other similar works, we do not
impose coercivity conditions on coefficients. We establish the continuous
dependence of the mild solution with respect to initial conditions and also
on coefficients. As corollaries of the continuity result, we derive sufficient
conditions for asymptotic stability of the solutions, we show that Yosida
approximations converge to the solution and we prove that solutions have
Markov property. Examples on stochastic partial differential equations
and stochastic delay differential equations are provided to demonstrate
the theory developed. The main tool in our study is an inequality which
provides a pathwise bound for the norm of stochastic convolution integrals.

Keywords: Stochastic evolution equations, monotone nonlinearity, sto-
chastic convolution integrals, Lévy processes.

MSC(2010): Primary: 60H15; Secondary: 60G51, 60H05, 47H05, 47J35.

1. Introduction

1.1. Motivation. Stochastic evolution equations in the simplest case are equa-
tions of the form

\[ dX_t = AX_t dt + f(X_t) dt + g(X_t) dW_t \]

in a Hilbert space where \( A \) is the infinitesimal generator of a \( C_0 \) semigroup
of linear operators and \( W_t \) is a Wiener process or more generally a martingale. The case that \( f \) and \( g \) are Lipschitz is classical and well studied (see [9]
and [20]). The extensions to non-Lipschitz coefficients, have been the subject
of many papers. There are two main approaches in the study of non-Lipschitz

* Corresponding author.

stochastic evolution equations. The first approach is the variational method and assumes some monotonicity and coercivity assumption on \( f, g \). For this approach, see [22, 27] and [29] for Wiener noise, [11] for general martingales and [4] for Lévy noise.

The second approach is the semigroup approach to semilinear stochastic evolution equations with monotone drift and assumes that \( f \) is semimonotone and \( g \) is Lipschitz, i.e. there exists a real constant \( M \) such that

\[
\langle f(x) - f(y), x - y \rangle \leq M\|x - y\|^2.
\]

This approach has first appeared in deterministic context in the works of Browder [3] and Kato [18] and has been extended to stochastic evolution equations in [34] and [37].

This approach is a generalization of the Lipschitz case, and this generalization is useful since there are natural semimonotone functions which are not Lipschitz; examples include decreasing real functions, such as \(-\sqrt{x}\), or the sum of a non differentiable decreasing function with a Lipschitz function. Figure 1 shows a semimonotone real function.

![Figure 1. A semimonotone function](image)

An advantage of the semigroup approach relative to the variational method is that it does not require the coercivity. There are important examples, such as stochastic partial differential equations of hyperbolic type with monotone nonlinear terms, for which the generator does not satisfy the coercivity property and hence the variational method is not directly applicable to these equations. But as is shown in Examples 6.3 and 6.5, this problem can be treated directly in semigroup setting.

There are other works with this approach, e.g. the exponential asymptotic stability of solutions in the case of Wiener noise has been studied in [14], stochastic delay evolution equations has been studied in [15], generalizing the previous results to stochastic functional evolution equations with coefficients depending on the past path of the solution is done in [17], a stopped version of (1.1) in case of Wiener noise has been studied in [13], the large deviation principle for the case of Wiener noise is studied in [5]. A limiting problem of such equations arising from random motion of highly elastic strings has been
considered in [33]. Finally, the stationarity of a mild solution to a stochastic evolution equation with a monotone nonlinear drift and Wiener noise is studied in [38].

In recent years some research has appeared on stochastic evolution equations with Lévy (jump) noise, see e.g. Peszat and Zabczyk [28], Albeverio, Mandrekar and Rüdiger [1] and Marinelli, Prévôt and Röckner [24] for the case of Lipschitz coefficients and Brzeźniak, Liu and Zhu [4] for coercive and monotone coefficients with variational method. There are a number of works that have considered monotone (dissipative) coefficients with additive Lévy noise, see e.g Peszat and Zabczyk [28].

We should mention the article by Marinelli and Röckner [25] which considers monotone nonlinear drift and multiplicative Poisson noise on certain function spaces and proves the existence, uniqueness and regular dependence of the mild solution on initial data. They don’t assume the linear growth condition on drift coefficient, but instead they impose an additional positivity assumption on the semigroup and the drift term is the Nemitsky operator associated with a real monotone function. They use a completely different method.

The main contribution of this article is Theorem 3.1 in Section 3 which shows the continuous dependence of the solution of (1.1) on initial conditions and coefficients. We mention below other works in the literature about continuous dependence. In the context of Wiener noise, [8] considers the case that the semigroup is analytic and \( f \) is locally Lipschitz, and shows that the solution is a continuous function of the noise coefficients. [34] generalizes this result to stochastic evolution equations with Wiener noise and monotone nonlinearity and shows that the solution depends continuously on initial condition and coefficients (including \( A \)). In the context of Poisson noise, [1] proves the continuous dependence on initial data and coefficients for the case of Lipschitz coefficients and [24] proves continuous dependence on initial data and under additional assumptions proves Gâteaux and Fréchet differentiability of the solution w.r.t initial data in the case of Lipschitz coefficients. We should mention the recent article [23] in which is shown the continuous dependence of the solution of (1.1) on all coefficients including \( A \) for the Lipschitz case. For equations with monotone coefficients, [25] proves the continuous dependence of the solution w.r.t initial condition. [16] proves the continuous dependence on coefficients in the case of Wiener noise with monotone nonlinearity.

1.2. The Main equation. Let \( H \) be a separable Hilbert space and \( S(t) \) a \( C_0 \)-semigroup of linear operators on \( H \) with generator \( A \). We are concerned with this equation,

\[
(1.1) \quad dX_t = AX_t dt + f(t, X_t) dt + g(t, X_t) dW_t + \int _E k(t, \xi, X_{t-}) \tilde{N}(dt, d\xi),
\]
where $W_t$ is a cylindrical Wiener process on another Hilbert space, $\tilde{N}(dt, d\xi)$ is a compensated Poisson random measure on a Banach space $U$ and independent of $W_t$. We assume $f$ is semimonotone and $g$ and $k$ are Lipschitz and have linear growth. In Section 2 the assumptions on coefficients are stated precisely.

The main results of this article are Theorem 3.1 and Corollary 3.2, proved in Section 3 which states that the solutions of equation (1.1) depend continuously, in an appropriate sense, on initial condition and also on coefficients. Several consequences of these results are also provided. In Corollary 3.3 a sufficient condition for exponential asymptotic stability of the solutions is derived. In Section 4 we introduce the well known Yosida approximations of equation (1.1) and show that the solutions of them converge to the solution of (1.1). In Section 5 the Markov property of the mild solutions is proved. We will provide some concrete examples to which our results apply. These examples consist of semilinear stochastic partial differential equations and a stochastic delay differential equation. Some of the statements have been presented previously in [30].

1.3. Stochastic Convolution Integrals. Let $Z(t)$ be a stochastic process. Consider the equation $dX(t) = AX(t)dt + dZ(t)$ with an initial condition $X(0)$. Since $A$ is not defined on all of $H$ this equation may have no solutions, for example when $X(0) \notin \text{Domain}(A)$. In the case that $Z(t)$ is an $H$-valued semimartingale, a weaker notion of solution for this equation, i.e. mild solution is defined as $X(t) = S(t)X(0) + \int_0^t S(t - s)dZ(s)$, where the integral is a stochastic integral. This is called a stochastic convolution integral (for the definition and properties of semimartingales and stochastic integration with respect to them the reader is referred to Metivier [26]).

Now we introduce the concept of mild solution for (1.1).

**Definition 1.1.** By a mild solution of equation (1.1) with initial condition $X_0$ we mean an adapted càdlàg process $X_t$ that satisfies

\begin{align*}
X_t &= S_tX_0 + \int_0^t S_{t-s}f(s, X_s)ds + \int_0^t S_{t-s}g(s, X_{s-s})dW_s \\
&\quad + \int_0^t \int E S_{t-s}k(s, \xi, X_{s-s})\tilde{N}(ds, d\xi).
\end{align*}

Inequalities concerning upper bounds for the norm of stochastic convolution integrals are useful in studying stochastic evolution equations. One of the first such inequalities was that of Kotelenez [19] which is a maximal inequality for stochastic convolution integrals. Kotelenez [19] uses this inequality to prove the existence of a càdlàg version for stochastic convolution integrals. From now on, we always assume that stochastic convolution integrals are càdlàg. Later Kotelenez [20] proved a stronger inequality which was a stopped Doob inequality.
Theorem 1.2 (Kotelenez, [20]). Assume $\alpha \geq 0$. There exists a constant $C$ such that for any $H$-valued càdlàg locally square integrable martingale $M_t$ we have

$$\mathbb{E} \sup_{0 \leq t \leq T} \left\| \int_0^t S_{t-s} dM_s \right\|^2 \leq Ce^{4\alpha T}\mathbb{E}[M_T].$$

Remark 1.3. Hamedani and Zangeneh [12] generalized this inequality to a stopped maximal inequality for $p$-th moment ($0 < p < \infty$) of stochastic convolution integrals.

Usual inequalities such as Theorem 1.2 concern the expectation of the norm of stochastic convolution integrals and because of the presence of monotone nonlinearity in equation (1.1), they are not applicable to (1.1). For this reason we will use the following pathwise inequality for the norm of stochastic convolution integrals which has been proved in Zangeneh [37].

Theorem 1.4 (Ito type inequality, Zangeneh [37]). Let $Z_t$ be an $H$-valued càdlàg locally square integrable semimartingale. If

$$X_t = S_t X_0 + \int_0^t S_{t-s} dZ_s,$$

then, a.s.

$$\|X_t\|^2 \leq e^{2\alpha t}\|X_0\|^2 + 2 \int_0^t e^{2\alpha(t-s)}(X_{s-}, dZ_s) + \int_0^t e^{2\alpha(t-s)}d[Z]_s,$$

where $[Z]_t$ is the quadratic variation process of $Z_t$.

2. The assumptions

Let $H$ be a separable Hilbert space with inner product $\langle \cdot, \cdot \rangle$. Let $S_t$ be a $C_0$ semigroup on $H$ with infinitesimal generator $A : D(A) \to H$. Furthermore we assume the exponential growth condition on $S_t$ holds, i.e. there exists a constant $\alpha$ such that $\|S_t\| \leq e^{\alpha t}$. If $\alpha = 0$, $S_t$ is called a contraction semigroup. We denote by $L_{HS}(K; H)$ the space of Hilbert-Schmidt mappings from a Hilbert space $K$ to $H$.

Definition 2.1. $f : H \to H$ is called semi-monotone if there exists a real constant $M$ such that

$$\forall x, y \in H : \langle f(x) - f(y), x - y \rangle \leq M\|x - y\|^2$$

and is called monotone if $M = 0$.

Note that semi-monotone condition is weaker than Lipschitz condition.

Definition 2.2. $f : H \to H$ is called demicontinuous if whenever $x_n \to x$, strongly in $H$ then $f(x_n) \to f(x)$ weakly in $H$. 
Let \((\Omega, \mathcal{F}, \mathcal{F}_t, P)\) be a filtered probability space. Let \((E, \mathcal{E})\) be a measurable space and \(N(dt, d\xi)\) a Poisson random measure on \(\mathbb{R}^+ \times E\) with intensity measure \(dt\nu(d\xi)\). Our goal is to study equation (1.1) in \(H\), where \(W_t\) is a cylindrical Wiener process on a Hilbert space \(K\) and \(\tilde{N}(dt, d\xi) = N(dt, d\xi) - dt\nu(d\xi)\) is the compensated Poisson random measure corresponding to \(N\). We assume that \(N\) and \(W_t\) are independent. We also assume the following,

**Hypothesis 2.3.**

\[(a): f(t, x, \omega) : \mathbb{R}^+ \times H \times \Omega \to H\] is measurable, \(\mathcal{F}_t\)-adapted, demicontinuous with respect to \(x\) and there exists a constant \(M\) such that
\[
\langle f(t, x, \omega) - f(t, y, \omega), x - y \rangle \leq M\|x - y\|^2,
\]

\[(b): g(t, x, \omega) : \mathbb{R}^+ \times H \times \Omega \to L_{HS}(K, H)\] and \(k(t, \xi, x, \omega) : \mathbb{R}^+ \times E \times H \times \Omega \to H\) are predictable and there exists a constant \(C\) such that
\[
\|g(t, x, \omega) - g(t, y, \omega)\|_{L_{HS}(K, H)}^2 + \int_E \|k(t, \xi, x) - k(t, \xi, y)\|^2 \nu(d\xi) \leq C\|x - y\|^2,
\]

\[(c): \text{There exists a constant } D\text{ such that}
\[
\|f(t, x, \omega)\|^2 + \|g(t, x, \omega)\|_{L_{HS}(K, H)}^2 + \int_E \|k(t, \xi, x)\|^2 \nu(d\xi) \leq D(1 + \|x\|^2),
\]

\[(d): X_0(\omega)\text{ is } \mathcal{F}_0\text{ measurable and square integrable.}
\]

The following theorem states that equation (1.1) has a unique mild solution. For the proof see [31].

**Theorem 2.4** (Existence and Uniqueness of the Mild Solution). Under the assumptions of Hypothesis 2.3, equation (1.1) has a unique square integrable càdlàg mild solution with initial condition \(X_0\).

### 3. The main result

**Theorem 3.1** (Continuity With Respect to Parameter \(I\)). Assume that for \(n = 0, 1, f_n(t, x, \omega), g_n(t, x, \omega)\) and \(k_n(t, \xi, x, \omega)\) satisfy Hypothesis 2.3 with the same constants. Let \(X^n_t\) be the unique mild solution of
\[
dX^n_t = AX^n_t dt + f_n(t, X^n_t) dt + g_n(t, X^n_t) dW_t + \int_E k_n(t, \xi, X^n_t) \tilde{N}(dt, d\xi),
\]
with initial condition $X^n_0$. Then,

\( \text{(3.1)} \quad E \sup_{0 \leq t \leq T} e^{-2\alpha t} \|X^1_t - X^0_t\|^2 \)

\[ \leq 2e^{C_{1}T}E \|X^1_0 - X^0_0\|^2 \\
+ 2e^{C_{1}T} \int_0^T e^{-2\alpha t}E \|f_1(t, X^1_t) - f_0(t, X^0_t)\|^2 dt \\
+ C_2 e^{C_{1}T} \int_0^T e^{-2\alpha t}E \|g_1(t, X^0_t) - g_0(t, X^0_t)\|^2 dt \\
+ C_2 e^{C_{1}T} \int_0^T \int_E e^{-2\alpha t}E \|(k_1(t, \xi, X^0_t) - k_0(t, \xi, X^0_t))\|^2 dt, \]

for $C_1 = 4M + 2 + C(8C_T^2 + 4)$ and $C_2 = 8C_T^2 + 4$ where $C_1$ is the universal constant in Burkholder-Davies-Gundy inequality.

Proof. First we consider the case that $\alpha = 0$. Subtract $X^1$ and $X^0$, 

\[ X^1_t - X^0_t = S_t(X^1_0 - X^0_0) \\
+ \int_0^t S_{t-s}(f_1(s, X^1_s) - f_0(s, X^0_s)) ds + \int_0^t S_{t-s}dM_s, \]

where

\[ M_t = \int_0^t (g_1(s, X^1_s) - g_0(s, X^0_s)) dW_s + \int_E (k_1(s, \xi, X^0_s) - k_0(s, \xi, X^0_s)) dN_s. \]

Applying Itô type inequality (Theorem 1.4), for $\alpha = 0$, to $X^1 - X^0$ we find

\( \text{(3.2)} \quad \|X^1_t - X^0_t\|^2 \leq \|X^1_0 - X^0_0\|^2 + \int_0^t \langle X^1_{s-} - X^0_{s-}, (f_1(s, X^1_s) - f_0(s, X^0_s)) \rangle ds \)

\[ + 2 \int_0^t \langle X^1_{s-} - X^0_{s-}, dM_s \rangle + [M], \]

We have

\[ A_t = \int_0^t \langle X^1_{s-} - X^0_{s-}, f_1(s, X^0_s) - f_1(s, X^0_s) \rangle ds \]

\[ + \int_0^t \langle X^1_{s-} - X^0_{s-}, f_1(s, X^0_s) - f_0(s, X^0_s) \rangle ds. \]

Using the monotonicity assumption and Cauchy-Schwartz inequality we have

\( \text{(3.3)} \quad A_t \leq M \int_0^t \|X^1_s - X^0_s\|^2 ds + \frac{1}{2} \int_0^t \|X^1_s - X^0_s\|^2 ds \)

\[ + \frac{1}{2} \int_0^t \|f_1(s, X^0_s) - f_0(s, X^0_s)\|^2 ds. \]
Applying Burkholder-Davies-Gundy inequality for \( p = 1 \) to term \( B_t \) we find

\[
E \sup_{0 \leq s \leq t} |B_s| \leq C_t E \left( \sup_{0 \leq s \leq t} \|X^1_s - X^0_s\| [M]^{\frac{1}{2}} \right),
\]

Note that the constant \( C_t \) in the Burkholder-Davies-Gundy inequality, does not depend on the coefficients or on the martingale. Now, by using the elementary inequality \( ab \leq \frac{1}{4} a^2 + b^2 \) we find,

\[
(3.4) \quad \leq \frac{1}{4} E \sup_{0 \leq s \leq t} \|X^1_s - X^0_s\|^2 + C_t^2 E[M]t.
\]

We have

\[
E[M]_t = \int_0^t E[\|g_1(s, X^1_s) - g_0(s, X^0_s)\|^2] ds
+ \int_0^t \int_E E[\|k_1(s, \xi, X^1_s) - k_0(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds
\leq 2 \int_0^t E[\|g_1(s, X^1_s) - g_1(s, X^0_s)\|^2 ds
+ 2 \int_0^t \int_E E[\|k_1(s, \xi, X^1_s) - k_1(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds
+ 2 \int_0^t \int_E E[\|k_1(s, \xi, X^1_s) - k_0(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds
\]

Using the Lipschitz assumption on \( g \) and \( k \) we find

\[
(3.5) \quad E[M]_t \leq 2C \int_0^t E[\|X^1_s - X^0_s\|^2] ds
+ 2 \int_0^t E[\|g_1(s, X^1_s) - g_0(s, X^0_s)\|^2 ds
+ 2 \int_0^t \int_E E[\|k_1(s, \xi, X^1_s) - k_0(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds.
\]

Substituting (3.3), (3.4) and (3.5) in (3.2), after cancellation we find

\[
E \sup_{0 \leq s \leq t} \|X^1_s - X^0_s\|^2 \leq C_1 \int_0^t E[\|X^1_s - X^0_s\|^2] ds + 2E[\|X^1_0 - X^0_0\|^2]
+ 2 \int_0^t E[\|f_1(s, X^0_s) - f_0(s, X^0_s)\|^2 ds
+ C_2 \int_0^t \int_E E[\|k_1(s, \xi, X^1_s) - k_0(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds
+ C_2 \int_0^t \int_E E[\|k_1(s, \xi, X^0_s) - k_0(s, \xi, X^0_s)\|^2 \nu(d\xi)] ds,
\]

where \( C_1 = 4M + 2 + C(8C_t^2 + 4) \) and \( C_2 = 8C_t^2 + 4 \).
Now applying Gronwall’s inequality the statement follows. Hence the proof for the case \( \alpha = 0 \) is complete. Now for the general case, we apply the following change of variables,
\[
\tilde{S}_t = e^{-\alpha t} S_t, \quad \tilde{f}(t,x,\omega) = e^{-\alpha t} f(t,e^{\alpha t} x,\omega), \quad \tilde{g}(t,x,\omega) = e^{-\alpha t} g(t,e^{\alpha t} x,\omega), \quad \tilde{k}(t,\xi,x,\omega) = e^{-\alpha t} k(t,\xi,e^{\alpha t} x,\omega).
\]
Note that \( \tilde{S}_t \) is a contraction semigroup. It is easy to see that \( \tilde{X}_t \) is a mild solution of equation (1.1) if and only if \( \tilde{X}_t = e^{-\alpha t} X_t \) is a mild solution of equation with coefficients \( \tilde{S}, \tilde{f}, \tilde{g}, \tilde{k} \).

As a consequence of Theorem 3.1 we prove that if the coefficients and initial conditions of a sequence of equations converge, then their mild solutions also converge to the mild solution of the limiting equation. The convergence that we prove is in a sense stronger than similar result in [1].

**Corollary 3.2** (Continuity With Respect to Parameter II). *Assume that for \( n = 0,1,2,\ldots, f_n, g_n, k_n \) and \( X_0^n \) satisfy Hypothesis 2.3 with the same constants and assume that for every \( t \in [0,T] \) and \( x \in H \) we have almost sure\( \bar{y} \)
\[
\begin{align*}
& f_n(t,x,\omega) \to f_0(t,x,\omega) \\
& g_n(t,x,\omega) \to g_0(t,x,\omega) \\
& \int_{\Omega} \|k_n(t,\xi,x,\omega) - k_0(t,\xi,x,\omega)\|^2 \nu(d\xi) \to 0 \\
& E\|X_0^n - X_0^0\|^2 \to 0.
\end{align*}
\]
Then
\[
E \sup_{0 \leq t \leq T} \|X_t^n - X_t^0\|^2 \to 0.
\]

**Proof.** Apply Theorem 3.1 to \( X^n \) and \( X^0 \). Note that by Hypothesis 2.3-(c) the integrands on the right hand side of (3.1) are dominated by a constant multiple of \((1 + \|X_0^n(\omega)\|^2)\), on the other hand by assumptions they tend to zero almost everywhere on \([0,T] \times \Omega\). Hence by the dominated convergence theorem, the right hand side of (3.1) tends to 0 and therefore
\[
E \sup_{0 \leq t \leq T} e^{-2\alpha t} \|X_t^1 - X_t^0\|^2 \to 0
\]
which implies the statement. □

As another consequence of Theorem 3.1 it follows that if the contraction coefficient of the semigroup is sufficiently negative, then all the mild solutions are exponentially stable.

**Corollary 3.3** (Exponential Stability). *Let \( X_t \) and \( Y_t \) be mild solutions of (1.1) with initial conditions \( X_0 \) and \( Y_0 \). Then
\[
E\|X_t - Y_t\|^2 \leq 2e^{\gamma t}E\|X_0 - Y_0\|^2
\]
for \( \gamma = 2\alpha + 4M + 2 + C(8C_1^2 + 4) \). In particular, if \( \gamma < 0 \) then all mild solutions are exponentially stable.

4. Yosida approximations

As another application of Theorem 3.1 we construct Lipschitz approximations of equation (1.1) known as Yosida approximations and prove that their solutions converge to the solution of (1.1). Since equations with Lipschitz coefficients can be solved numerically, this can be used as a scheme for numerical solution of (1.1).

In this section we assume \( f : H \to H \) satisfies a condition stronger than monotonicity which is maximal monotonicity. This concept in its most generality is defined for subsets of \( X \times X^* \) in which \( X \) is a Banach space. For a detailed treatment of this concept see [2].

**Definition 4.1.** \( A \subset X \times X^* \) is called monotone, if for any \((x_1, y_1), (x_2, y_2) \in A\),

\[
(y_2 - y_1, x_2 - x_1) \leq 0
\]

and is called maximal monotone if it is monotone and is not properly contained in any monotone set.

Note that any operator \( f : X \to X^* \) can be viewed as a subset of \( X \times X^* \) and hence the concept of maximal monotonicity is defined for it, especially since \( H \) is a Hilbert space, maximal monotonicity makes sense for operators \( f : H \to H \).

Maximal monotonicity is not very restrictive as the following theorem shows that any monotone operator with a weak continuity assumption called hemicontinuity is maximal monotone.

**Definition 4.2.** \( f : H \to H \) is called hemicontinuous if for any \( x, y \in H \), \( f(x + ty) \) is continuous as a function of \( t \in \mathbb{R} \) (in other words \( f \) is continuous in each direction).

**Theorem 4.3** ([2], page 45, Theorem 1.3). Let \( f : H \to H \) be monotone and hemicontinuous, then it is maximal monotone.

Let \( f : H \to H \) be a maximal monotone operator. Then we follow [2] to define for \( \lambda > 0 \),

\[
I_\lambda = (I - \lambda f)^{-1} \\
f_\lambda = \lambda^{-1}(I_\lambda - I)
\]

Note that with our notation, \(-f\) is maximal monotone in the sense of [2]. Some of the important properties of \( f_\lambda \) are listed in the following proposition.

**Proposition 4.4** ([2], page 49, Proposition 1.3). Let \( f : H \to H \) be maximal monotone. Then

(i): \( f_\lambda \) is monotone and Lipschitz on \( H \).
(ii): For any $x \in H$, $\|f_\lambda(x)\| \leq \|f(x)\|$. 

(iii): For any $x \in H$, $\lim_{\lambda \to 0} f_\lambda(x) = f(x)$ strongly in $H$.

Now we are ready to state and prove the main theorem of this section.

**Theorem 4.5.** Let $f$ be maximal monotone and let $X^\lambda$ be the mild solution of

\[ dX^\lambda_t = AX^\lambda_t dt + f_\lambda(X^\lambda_t)dt + g(t, X^\lambda_t) dW_t + \int_E k(t, \xi, X^\lambda_{t^-}) d\tilde{N}(dt,d\xi), \]

then we have

\[ \lim_{\lambda \to 0} \mathbb{E} \left( \sup_{0 \le s \le t} \|X^\lambda_s - X_s\|^2 \right) = 0 \]

**Proof.** By Proposition 4.4-(i), $f_\lambda$’s are monotone and continuous and by (ii) they have linear growth condition with the same constant as $f$. Hence the assumptions of Corollary 3.2 are satisfied and the statement follows. \qed

**Remark 4.6.** The hemicontinuity assumption holds for many monotone operators, especially for Nemitsky operators associated with decreasing continuous real functions, since as will be mentioned in Section 6 these operators are in fact continuous and hence hemicontinuous on $L^2(D)$ and therefore they are maximal monotone by Theorem 4.3. Hence Theorem 4.5 could be applied to examples of Section 6.

5. Markov property

In this section we assume that $f$, $g$ and $k$ are deterministic functions and satisfy Hypothesis 2.3. Let $0 \leq s \leq t$ and $\eta : \Omega \to H$ be $\mathcal{F}_s$-measurable and square integrable. We denote by $X(s, \eta, t)$ the value at time $t$ of the solution of (1.1) starting at time $s$ from $\eta$. Let $B_b(H)$ be the space of real valued bounded measurable functions on $H$. For $\varphi \in B_b(H)$ and $x \in H$ define

\[ P_{s,t} \varphi(x) := \mathbb{E}(\varphi(X(s, x, t))). \]

$P_{s,t}$ is called the transition semigroup.

**Theorem 5.1** (Markov Property). For $0 \leq r \leq s \leq t$ and $\varphi \in B_b(H)$ we have almost surely

\[ \mathbb{E}(\varphi(X(s, x, t)|\mathcal{F}_s)) = P_{s,t} \varphi(X(s, x, s)) \quad \mathbb{P} - \text{almost sure}. \]

**Proof.** Let $C_b(H)$ denote the set of real valued bounded continuous functions on $H$. It suffices to prove the theorem for $\varphi \in C_b(H)$ since every $\varphi \in B_b(H)$ is the pointwise limit of a uniformly bounded sequence in $C_b(H)$. Fix $r$, $s$ and $t$. We claim that for any square integrable random variable $\eta(\omega)$ which is $\mathcal{F}_s$ measurable, we have

\[ \mathbb{E}(\varphi(X(s, \eta, t))|\mathcal{F}_s) = P_{s,t} \varphi(\eta(\omega)) \quad \mathbb{P} - \text{almost sure}. \]
We first prove the claim for the case that $\eta$ has a simple form $\eta = \sum y_k \chi_{A_k}$, where $y_k \in H$ and $A_k \in \mathcal{F}_s$ form a partition of $\Omega$. We have
\[
E(\varphi(X(s, \eta, t))|\mathcal{F}_s) = \mathbb{E}\left(\sum \varphi(X(s, y_k, t))\chi_{A_k}|\mathcal{F}_s\right) = \sum \chi_{A_k} E(\varphi(X(s, y_k, t))|\mathcal{F}_s).
\]
Note that $X(s, y_k, t)$ is independent of $\mathcal{F}_s$, hence
\[
= \sum \chi_{A_k} \mathbb{E}(\varphi(X(s, y_k, t))) = \sum \chi_{A_k} P_{s,t}\varphi(y_k) = P_{s,t}\varphi(\eta(\omega)).
\]
Now for general $\eta$ choose a sequence $\eta_n$ of simple random variables such that tend to $\eta$ in $L^2(\Omega)$ and almost surely. We then have
\[
E(\varphi(X(s, \eta_n, t))|\mathcal{F}_s) = P_{s,t}\varphi(\eta_n(\omega)) \quad \mathbb{P} - \text{almost sure}.
\]
Now let $n \to \infty$. By continuity with respect to initial conditions, the left hand side converges to $\mathbb{E}(\varphi(X(s, \eta, t))|\mathcal{F}_s)$ and the right hand side converges to $P_{s,t}\varphi(\eta(\omega))$ and (5.1) follows. Now in (5.1) let $\eta(\omega) = X(r,x,s)$. By uniqueness of solution we have $X(r,x,t) = X(s,X(r,x,s),t)$ and the theorem follows. $\Box$

6. Some examples

In this section we provide some concrete examples of semilinear stochastic evolution equations with monotone nonlinearity and Lévy noise which the results of previous sections could be applied. The examples consist of stochastic partial differential equations of parabolic and hyperbolic type and a stochastic delay differential equation.

Example 6.1 (Stochastic reaction-diffusion equations with multiplicative Poisson noise). In this example we consider a class of semilinear stochastic evolution equations with multiplicative Poisson noise. Let $\mathcal{D}$ be a bounded domain with a smooth boundary in $\mathbb{R}^d$. Consider the equation,

\[
\begin{aligned}
\left\{ \begin{array}{ll}
\frac{du(t)}{dt} = A u(t) dt + f(u(t,x)) dt + \eta(u(t)) dt \\
+ \int_{E} k(t, \xi, u(t^-, x)) N(dt, d\xi)
\end{array} \right.
\end{aligned}
\]

\[ u(0) = u_0. \]

where $A$ is the generator of a $C_0$ semigroup on $L^2(D)$, $f: \mathbb{R} \to \mathbb{R}$ is a continuous decreasing function with linear growth and $k: [0,T] \times E \times \mathbb{R} \times \Omega \to \mathbb{R}$ is measurable and satisfies the Lipschitz condition
\[
\mathbb{E} \int_{E} |k(s, \xi, u) - k(s, \xi, v)|^2 \mu(d\xi) \leq C|u - v|^2
\]
and the linear growth condition
\[ \mathbb{E} \int_E |k(s, \xi, u)|^2 \mu(d\xi) \leq D(1 + |u|^2) \]
and \(u_0 \in L^2(D)\). We prove that equation (6.1) has a unique mild solution in \(L^2(D)\).

We show that equation (6.1) satisfies the assumptions of Theorem 2.4. Let \(H = L^2(D)\). We denote the Nemitsky operator associated with a function \(f: \mathbb{R} \to \mathbb{R}\) by the same symbol. Since \(f\) and \(k\) are continuous and have linear growth, by Theorem (2.1) of Krasnosel’ski [21], the associated Nemitsky operators define continuous operators from \(L^2(D)\) to \(L^2(D)\) and have linear growth. Verifying the other assumptions is straightforward. Hence applying Theorem 2.4 we conclude that equation (6.1) has a unique mild solution in \(L^2(D)\) and Theorem 3.1 implies that the solution map \(u_0 \mapsto u\) is Lipschitz in the sense that
\[ \mathbb{E} \sup_{t \leq T} \|u(t) - v(t)\|^2_{L^2(D)} \leq C\|u_0 - v_0\|^2_{L^2(D)}. \]

We also can use Theorem 4.5 to build Lipschitz approximations of equation (6.1) and solve them numerically to approximate the solution of (6.1).

**Remark 6.2.**

1. Equation (6.1) is the same as the main equation studied in [25] but the assumptions on coefficients are different.
2. As important examples for the operator \(A\), one can denote any second order elliptic operator on \(D\).
3. The same results hold if we add a Wiener noise term with Lipschitz coefficient.
4. It is straightforward to generalise this example to the case that \(f\) and \(k\) depend also on \(x\) and in that case it suffices to assume that \(f(x, u)\) and \(k(x, u)\) satisfy Caratheodory condition, i.e. they are continuous with respect to \(u\) for almost all \(x \in D\) and are measurable with respect to \(x\) for all values of \(u\).

**Example 6.3 (Second Order Stochastic Hyperbolic Equations with Lévy noise).**

In this example we consider a hyperbolic SPDE with Lévy noise. Let \(D\) be a bounded domain with a smooth boundary in \(\mathbb{R}^d\), Consider the initial boundary value problem,

\[
\begin{cases}
\frac{\partial^2 u}{\partial t^2} = \Delta u - 3 \frac{\partial u}{\partial t} + u(t, x) \frac{\partial Z}{\partial t} & \text{on } [0, \infty) \times D \\
u = 0 & \text{on } [0, \infty) \times \partial D \\
u(0, x) = u_0(x) & \text{on } D \\
\frac{\partial \nu}{\partial \nu}(0, x) = 0 & \text{on } D,
\end{cases}
\]

where \(Z(t)\) is a real valued square integrable Lévy process and \(u_0(x) \in L^2(D)\) is the initial condition. We apply the results of previous sections and conclude
that this equation has a unique mild solution in $H^1(D)$ (Sobolev space of weakly differentiable functions on $D$ with derivative in $L^2(D)$). One can replace $-\sqrt{\mathcal{F}}$ by any continuous decreasing real function with linear growth. We generalize this equation as follows:

$$
(6.3) \quad \begin{cases}
\frac{\partial^2 u}{\partial t^2} (t,x) = \Delta u + f(u, \frac{\partial u}{\partial t}) + g_i(u(t^-, x)) \frac{\partial W_i}{\partial t} + k_j(u(t^-, x)) \frac{\partial Z_j}{\partial t} & \text{on } [0, \infty) \times D
\end{cases}
$$

on $[0, \infty) \times \partial D$. 

where $W_i(t), i = 1, \ldots, m$ are standard Wiener processes in $\mathbb{R}$ and $Z_j(t), j = 1, \ldots, n$ are pure jump Lévy martingales in $\mathbb{R}$ with intensity measures $\nu_j(d\xi)$ and $u_0(x) \in L^2(D)$.

Moreover assume that, 

**Hypothesis 6.4.** 

(a): $f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ is measurable and continuous and is Lipschitz w.r.t first variable and semimonotone w.r.t second variable, i.e there exist constants $M$ and $C$ such that for any $a, a_1, a_2, b, b_1, b_2 \in \mathbb{R}$,

$$
\lVert f(a_1, b) - f(a_2, b) \rVert \leq C \lVert a_1 - a_2 \rVert.
$$

$$
f(a, b_1) - f(a, b_2) \leq M(b_1 - b_2).
$$

(b): There exists a constant $C > 0$ such that for any $x \in D$ and $a, b \in \mathbb{R}$,

$$
\sum_{i=1}^{m} \lvert g_i(x, a) - g_i(x, b) \rvert^2 + \sum_{j=1}^{n} \lvert k_j(x, a) - k_j(x, b) \rvert^2 \leq C \lvert a - b \rvert^2.
$$

(c): There exists a constant $D > 0$ such that for any $a, b \in \mathbb{R}$,

$$
\lvert f(a, b) \rvert + \sum_{i=1}^{m} \lvert g_i(a) \rvert + \sum_{j=1}^{n} \lvert k_j(a) \rvert \leq D(1 + \lvert a \rvert + \lvert b \rvert).
$$

Note that $\Delta$ is self-adjoint and negative definite on $L^2$. Moreover, we have $D((-\Delta)^{\frac{1}{2}}) = H^1(D)$.

Hence by Lemma B.3 of [28], the operator

$$
\mathcal{A} = \begin{pmatrix}
0 & 1 \\
\Delta & 0 
\end{pmatrix}
$$

generates a $C_0$ semigroup of contractions on $H$.

Let $K = E = \mathbb{R}$. We also define for $(u, v) \in H$ and $\phi \in K$ and $\xi \in E$,

$$
\tilde{f}(u,v) = \begin{pmatrix}
0 \\
\tilde{f}(u(x), v(x))
\end{pmatrix}, \tilde{g}(u,v)(\phi) = \begin{pmatrix}
0 \\
g(u(x))\phi
\end{pmatrix},
$$
\[ \tilde{k}(\xi, u, v) = \begin{pmatrix} 0 \\ k(u(x))\xi \end{pmatrix}. \]

We claim that \( \tilde{f}, \tilde{g} \) and \( \tilde{k} \) satisfy Hypothesis 2.3. The continuity of \( \tilde{f}, \tilde{g} \) and \( \tilde{k} \) follows as in example 6.1 (note that the values of these functions are essentially in \( L^2(D) \) and that \( H^1(D) \) embeds continuously in \( L^2(D) \)). We show the semimonotonicity condition, the other conditions are straightforward.

\[
\langle \tilde{f}(u_1, v_1) - \tilde{f}(u_2, v_2), \begin{pmatrix} u_1 \\ v_1 \end{pmatrix} - \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} \rangle = \langle f(u_1, v_1) - f(u_2, v_2), v_1 - v_2 \rangle = \langle f(u_1, v_1) - f(u_2, v_2), v_1 - v_2 \rangle + \langle f(u_1, v_2) - f(u_2, v_2), v_1 - v_2 \rangle
\]

where by Hypothesis 6.9-(a) and Schwartz inequality

\[
\leq M\|v_1 - v_2\|^2 + C\|u_1 - u_2\|\|v_1 - v_2\|
\leq (M + C) \left( \|u_1 - u_2\|^2 + \|v_1 - v_2\|^2 \right).
\]

Hence Hypothesis 2.3-(a) holds with constant \( M + C \). Now, if we let

\[ X(t) = \begin{pmatrix} u(t) \\ \partial u(t) \end{pmatrix} \]

then equation (6.5) can be written as

\[ dX(t) = AX(t)dt + \tilde{f}(X(t))dt + \tilde{g}(X(t^-))dW_t + \int_E \tilde{k}(\xi, X(t^-))\tilde{N}(dt, d\xi) \]

and hence by Theorem 2.4 has a mild solution \( u(t, x, \omega) \) with values in \( H \) and with càdlàg trajectories.

**Example 6.5 (SPDE with Space-Time Noise).** In this example we would like to consider a SPDE with infinite dimensional noise. A natural candidate for infinite dimensional noise is space-time white noise, but it can be shown that in dimensions greater than one, even the equation

\[ \frac{\partial u}{\partial t}(t, x) = \Delta u(t, x) + \tilde{W}(t, x) \]

does not have a function valued solution ( [28], Remark 12.2). In order to guarantee the existence of solution we assume that coefficients are operators on certain function spaces.

Let \( D \) be as in Example 6.1. Consider the initial boundary value problem on \( D \),

\[
\begin{cases} \frac{\partial u}{\partial t} = \Delta u + f(u(t)) + g(u(t^-))\frac{\partial W}{\partial t} + k(u(t^-))\frac{\partial Z}{\partial t} & \text{on } [0, \infty) \times \mathcal{D} \\ u = 0 & \text{on } [0, \infty) \times \partial \mathcal{D} \\ u(0, x) = 0 & \text{on } \mathcal{D} \end{cases}
\]
where $W_t$ is a cylindrical Wiener process on $L^2(D)$ and $Z_t$ is a pure jump Lévy martingale on $L^2(D)$, and by $u(t)$ we mean $u(t, \cdot)$.

Let $n$ be an integer. We wish to solve this equation in the function space $H_n$ introduced in Walsh [32]. Let $\{\phi_j\}$ be the complete orthonormal basis for $L^2(D)$ consisting of eigenfunctions of $\Delta$ with Dirichlet boundary condition and $-\lambda_j < 0$ be the corresponding eigenvalues. Let $H_n$ be the Hilbert space that has as a complete orthonormal basis the set $\{e_j = (1 + \lambda_j)^{-\frac{1}{2}} \phi_j\}$. Obviously $H_0 = L^2(D)$ and the spaces $H_n$ can be continuously embedded in each other as 
$$\cdots \subset H_n \subset \cdots \subset H_1 \subset L^2(D) \subset H_{-1} \subset \cdots \subset H_{-n} \subset \cdots .$$

Assume moreover,

**Hypothesis 6.6.**

(a): $f : H_n \to H_n$ is measurable, demicontinuous and there exists a constant $M$ such that for any $u, v \in H_n$,
\[ (f(u) - f(v), u - v) \leq M \|u - v\|^2, \]

(b): $g : H_n \to L(HS(L^2(D), H_n))$ and $k : H_n \to L(L^2(D), H_n)$ are Lipschitz.

(c): There exists a constant $D$ such that for $u \in H_n$,
\[ \|f(u)\|^2 + \|g(u)\|^2 + \|k(u)\|^2 \leq D(1 + \|u\|^2), \]

$A$ generates a $C_0$ semigroup $S_t$ on $H$ where $S_t e_j = e^{-t\lambda_j} e_j$. Let $K = E = L^2(D)$ and let $\tilde{N}(dt, d\xi)$ be the compensated Poisson random measure on $E$ corresponding to the Lévy process $Z_t$ with intensity measure $\nu(d\xi)$, and define
\[ \tilde{k}(\xi, u) := k(u)(\xi). \]

Now, it is easy to verify that $f, g$ and $\tilde{k}$ satisfy Hypothesis 2.3 and therefore equation (6.4) can be written in the form of equation (1.1) with initial condition $0$ and hence (6.4) has a mild solution $u(t, x, \omega)$ with values in $H_n$ and with càdlàg trajectories.

**Remark 6.7.** In Hypothesis 6.6-(b) one can replace the condition on $g$ by
\[ g : H_n \to L(W^{-p,2}(D), H_n) \]
where $p > \frac{d}{2}$ is a real number, since the embedding $L^2(D) \hookrightarrow W^{-p,2}(D)$ is Hilbert-Schmidt (see Walsh [32] page 334).

**Remark 6.8.** One can use the same arguments as above and the technique used in Example 6.3 to study the second order hyperbolic equation,
\[
\begin{aligned}
& \frac{\partial^2 u(t, x)}{\partial t^2} = \Delta u + f(u(t), \frac{\partial u}{\partial t}) + g(u(t^-)) \frac{\partial W}{\partial t} + k(u(t^-)) \frac{\partial Z}{\partial t} \\
& u = 0 \\
& u(0, x) = 0 \\
& \frac{\partial u}{\partial t}(0, x) = 0
\end{aligned}
\]
on $[0, \infty) \times D, [0, \infty) \times \partial D, D, \partial D$. 

Hypothesis 6.9. (a): $f : H_{n+1} \times H_n \to H_n$ is measurable, demicontinuous and there exists constants $M$ and $C$ such that for any $u, u_1, u_2 \in H_{n+1}, v, v_1, v_2 \in H_n$,

$$
\langle f(u, v_1) - f(u, v_2), v_1 - v_2 \rangle \leq M\|v_1 - v_2\|^2,
$$

$$
\|f(u_1, v) - f(u_2, v)\| \leq C\|u_1 - u_2\|.
$$

(b): $g : H_{n+1} \to L_{HS}(L^2(D), H_n)$ and $k : H_{n+1} \to L(L^2(D), H_n)$ are Lipschitz.

(c): There exists a constant $D$ such that for $u \in H_{n+1}, v \in H_n$

$$
\|f(u, v)\|^2 + \|g(u)\|^2 + \|k(u)\|^2 \leq D(1 + \|u\|^2 + \|v\|^2).
$$

It follows that under Hypothesis 6.9, the equation (6.5) has a mild solution $u(t, x, \omega)$ with values in $H_{n+1}$ and with càdlàg trajectories.

Example 6.10 (Stochastic Delay Equations). Consider the following delay differential equation in $\mathbb{R}$,

$$(6.6) \begin{cases} dx(t) = \left( \int_{t-h}^{0} x(t + \theta) \right) dt - \sqrt{x(t)} dt + x(t) dZ_t \\ x(\theta) = \sin(\pi \theta), \quad \theta \in (-h, 0], \end{cases}$$

where $Z_t$ is a real valued square integrable Lévy process. We apply the results of previous sections and show that this equation has a unique càdlàg mild solution. Moreover, $-\sqrt{x}$ can be replaced by any continuous decreasing real function with linear growth. We generalize the above equation as follows:

$$(6.7) \begin{cases} dx(t) = \left( \int_{-h}^{0} \mu(d\theta) x(t + \theta) \right) dt + f(x(t)) dt + g(x(t)) dW_t + k(x(t)) dZ_t \\ x(\theta) = \psi(\theta), \quad \theta \in (-h, 0]. \end{cases}$$

where $h > 0$, $\mu$ is a measure on $(-h, 0]$ with finite variation, $W_t$ is a standard Wiener process in $\mathbb{R}$, $Z_t$ is a pure jump Lévy martingale in $\mathbb{R}$ and $\psi(\theta) \in L^2((-h, 0])$. Moreover assume that,

Hypothesis 6.11. (a): $f : \mathbb{R} \to \mathbb{R}$ is continuous and there exists a constant $M$ such that for any $a < b$,

$$
|f(a) - f(b)| \leq M(a - b),
$$

(b): $g : \mathbb{R} \to \mathbb{R}$ and $k : \mathbb{R} \to \mathbb{R}$ are Lipschitz.

(c): There exists a constant $D$ such that for $a \in \mathbb{R}$,

$$
|f(a)|^2 + |g(a)|^2 + |k(a)|^2 \leq D(1 + a^2).
$$
Remark 6.12. Peszat and Zabczyk [28] have studied this delay differential equation with Lipschitz coefficients. We have replaced Lipschitzness of \( f \) by the weaker assumption of semimonotonicity.

Let \( H = \mathbb{R} \times L^2(\mathcal{H}, 0) \) and define the operator \( A \) on \( H \) by

\[
A \left( \begin{array}{c} u \\ v \end{array} \right) = \left( \begin{array}{c} \int_{-h}^{0} v(\theta) \mu(d\theta) \\ \partial_v \end{array} \right).
\]

According to Da Prato and Zabczyk [9], Proposition A.25, the operator \( A \) with domain

\[
D(A) = \left\{ \left( \begin{array}{c} u \\ v \end{array} \right) \in H : v \in W^{1,2}(-h, 0), v(0) = u \right\}
\]

generates a \( C_0 \) semigroup \( S_t \) on \( H \). Let \( K = E = \mathbb{R} \) and let \( \tilde{N} \) be the compensated Poisson random measure associated with \( Z_t \). Define for \( \left( \begin{array}{c} u \\ v \end{array} \right) \in H \) and \( \xi \in \mathbb{R}, \)

\[
\tilde{f}(u, v) = \left( \begin{array}{c} f(u) \\ 0 \end{array} \right), \tilde{g}(u, v) = \left( \begin{array}{c} g(u) \\ 0 \end{array} \right), \tilde{k}(\xi, u, v) = \left( \begin{array}{c} \xi k(u) \\ 0 \end{array} \right).
\]

It is easy to verify that \( \tilde{f}, \tilde{g} \) and \( \tilde{k} \) satisfy Hypothesis 2.3. Now, if we let

\[
X(t) = \left( \begin{array}{c} x(t) \\ x_t \end{array} \right)
\]

where \( x_t(\theta) = x(t + \theta) \) for \( \theta \in (-h, 0] \), then equation (6.7) can be written as

\[
dX(t) = AX(t)dt + \tilde{f}(X(t))dt + \tilde{g}(X(t^-))dW_t + \int_E \tilde{k}(\xi, X(t^-))\tilde{N}(dt, d\xi)
\]

with initial condition

\[
X(0) = \left( \begin{array}{c} \psi(0) \\ \psi \end{array} \right)
\]

and hence by Theorem 2.4 has a unique mild solution \( x(t, \omega) \) with càdlàg trajectories and the solution depends continuously on initial condition.

Acknowledgments

The authors wish to thank Professor Carlo Marinelli for introducing them to the valuable article [25].
